

B05 Gate C Protected Review - Travel Bookings

Cloud architecture evidence, operations and changed retry

Protected review - saved genuine Gate attempt required

Open only after the matching Gate attempt is saved. Diagnose, repair, close the review and produce changed evidence. Later Gates remain explicitly assigned fresh reassessments.

Non-negotiable case evidence

- Booking SQL is private/on-prem and needs a secure connection boundary; flight API, partner SFTP, cloud event stream and Azure Blob do not automatically share that requirement.
- Flight status has 5 min SLA and web events <5 min; booking transactions 10 min; partner/finance daily. Tightest freshness drives incident priority but not every source schedule.
- Ops, finance and support require different detail; pipeline service identity is nonhuman least privilege; external partner gets no workspace by default.
- Incidents: booking gateway outage, SFTP 8 hours late, flight API schema rename. Require stale-data/partial-publish decisions, schema quarantine/replay and consumer communication.
- Architecture must distinguish operational availability from analytical reporting and avoid hidden paid-tenant click dependencies in the assessment.

Architecture and operations rubric

- Start from location, format, sensitivity, freshness, failure tolerance and consumer need before naming Fabric items/services.
- Separate storage from compute and choose copy/reference/shortcut only with a workload reason.
- Distinguish private/on-prem connectivity from ordinary cloud access; name the network/gateway owner where applicable.
- Separate workspace/item control-plane permissions from data-plane access. Use human groups and nonhuman identities deliberately.
- For every freshness SLA, define schedule/trigger, tolerance, monitoring signal, owner, recovery/backfill and post-recovery validation.
- For security/schema incidents, state block/quarantine/partial-publish behavior and lineage/consumer impact.
- Include a rejected alternative and objective acceptance tests in the handoff.

Critical failures

- Ungrounded service selection or “Fabric does everything” reasoning.
- Gateway invented for cloud sources or omitted for a private source.
- Broad Contributor/Admin used as a data-access shortcut.
- One refresh schedule used despite different SLAs.
- Incident has no owner, recovery, post-validation or stale-data communication.
- External user receives confidential detail or broad workspace access without justification.
- Hidden live-tenant dependency required to pass a reasoning assessment.

Repair and changed retry route

- Keep the original attempt append-only.
- Open only this matching review after the saved genuine attempt.
- Repair the smallest weak competency using targeted remediation.
- Close the review and solve a changed micro-scenario with different source/network/security/freshness facts.
- Save the changed evidence. Gate B/C still require the existing explicit fresh full-retest assignment.

Next route

PASS -> B06. Unresolved critical failure keeps B05 blocked; there is no hidden Gate D.
